

Using and Evaluating Formulas

A **formula** is an equation that relates one quantity to one or more other quantities. For instance, the area of a rectangle is given by the formula

$$\text{Area} = (\text{base})(\text{height}) \quad \text{or} \quad A = bh.$$

Study Tip

Another formula for the area of a rectangle is “length times width.”

$$A = \ell w$$

Common Area Formulas

Square: “side squared”

Rectangle: “base times height”

EXAMPLE 4 Buying Floor Tiles

12 in.

12 in.

Ceramic tile has been around for at least 4000 years. Tiled surfaces have been found in the ruins of Egypt, Babylon, and Greece.

You are buying tiles for your kitchen floor. The room is 8 feet by 12 feet. The tiles are 12-inch squares that cost \$8.97 each. The tiles come in boxes of 15. You should order an extra 20 tiles to allow for waste.

- How many boxes should you order?
- What is the total cost of your order?

SOLUTION

- The area of the room is 8×12 , or 96 square feet. So, you need 96 tiles plus an extra 20 tiles for waste. This is a total of 116 tiles. Because there are 15 tiles in a box, you should order 8 boxes, giving you 120 tiles.
- The total cost of your order is

$$\begin{array}{cc} \boxed{\text{Number of tiles}} & \boxed{\text{Cost per tile}} \\ \downarrow & \downarrow \\ 120 \times 8.97 & = \$1076.40. \end{array}$$
